

ABSTRACT

An information provision control system is provided whereby preferential information can be provided only to the employees of an affiliated enterprise, using an Internet home page. An authentication server stores the domain names of terminals of affiliated parties who are permitted to obtain information stored in a contents server. Moreover, the authentication server, when the contents server is accessed, compares the domain name of the accessed terminal with stored domain names of terminals of affiliated parties, and judges if the terminal is the terminal of an affiliated party. A member management server, in the case where the terminal is the terminal of the affiliated party, limits the range of information to be provided according to the affiliated party.
